Identity and access management (IAM) systems are necessary for authenticating and authorizing access to your environment. However, their mismanagement is one of the leading causes of breaches and insider threats today. Engineering teams must rapidly provision identities and permissions to keep pace with infrastructure growth—consequently, the ratio of non-human or machine identities to every human identity is also increasing at a substantial rate. This complexity makes it difficult to keep IAM configurations up to date and protect your environment against IAM-based attacks.

Catch up on Keynote highlights from DASH

we'll show you how Datadog CIEM enables you to secure your infrastructure from IAM-based attacks.

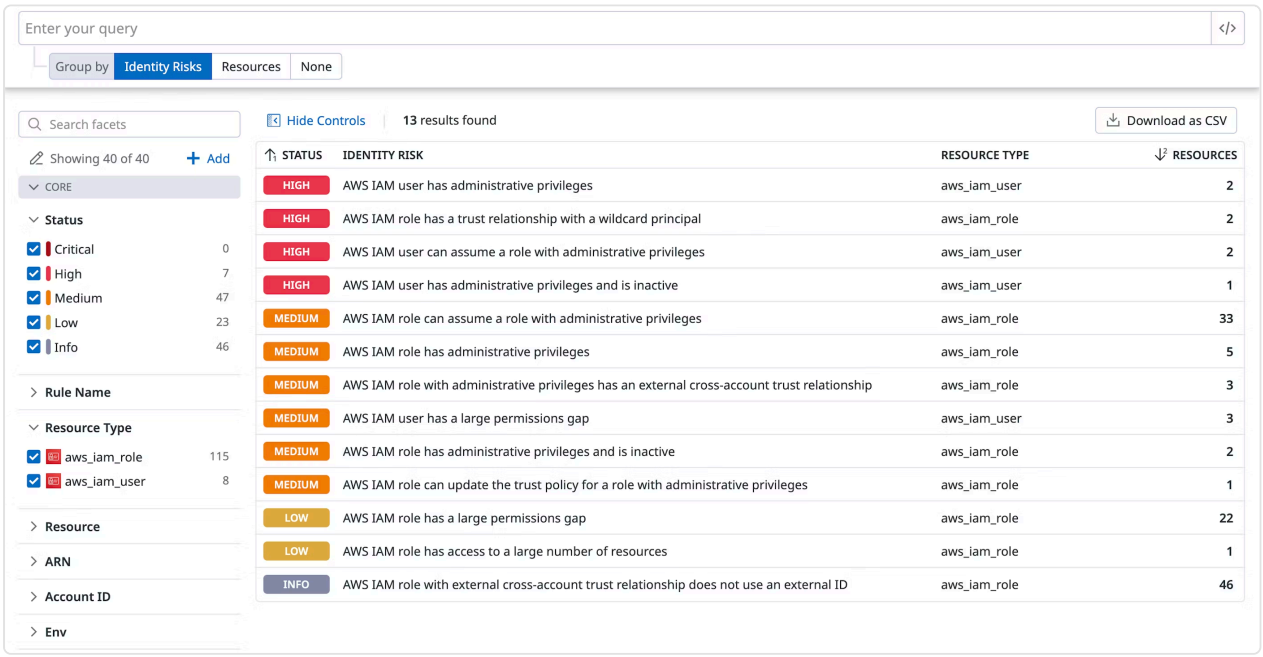

Surface identity risks based on best practices and research

Datadog CIEM enables you to identify and address identity risks in order to reduce their impact. It accomplishes this by leveraging your environment's current IAM configuration and resource usage—along with the latest industry best practices and attack vectors—to automatically detect and prioritize identity risks for users, roles, groups, policies, EC2 instances, and Lambda functions. The types of risks that Datadog CIEM detects include:

- Administrative privileges
- Permissions gaps
- Large blast radius
- Privilege escalation
- Cross-account access

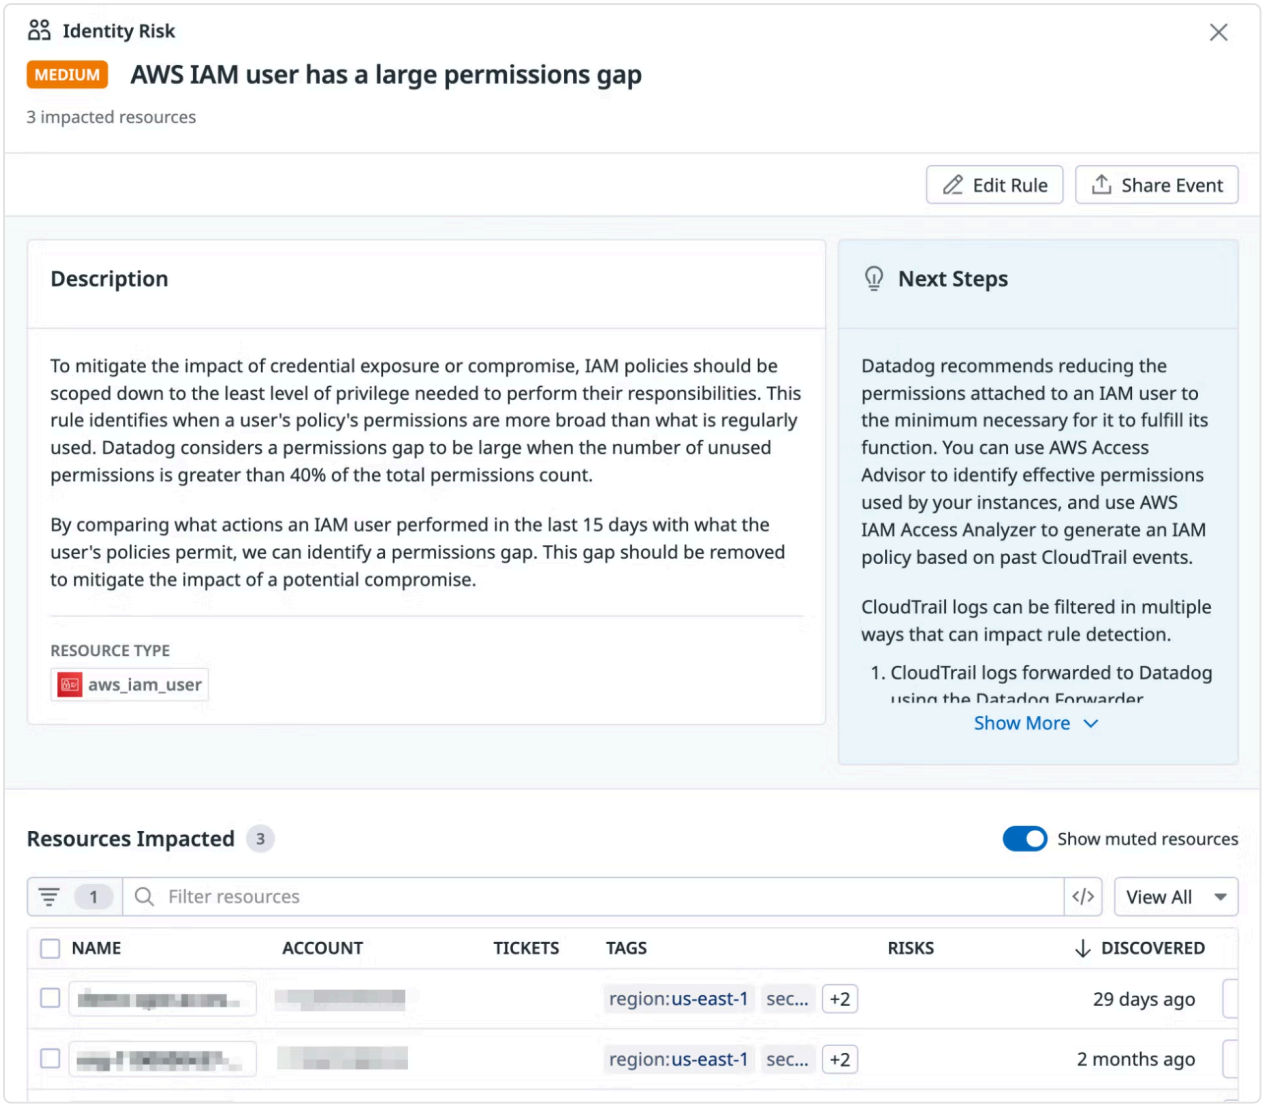

Datadog's Security Research team routinely curates the list of identity risks that Datadog CIEM detects so that our users can remain proactive in their defenses as new identity-based risks are identified.

As you sort through your IAM risk findings, you can review individual at-risk resources or address one identity risk at a time by grouping all resources (e.g., users, roles, groups, policies) that carry that risk, as seen in the following screenshot.

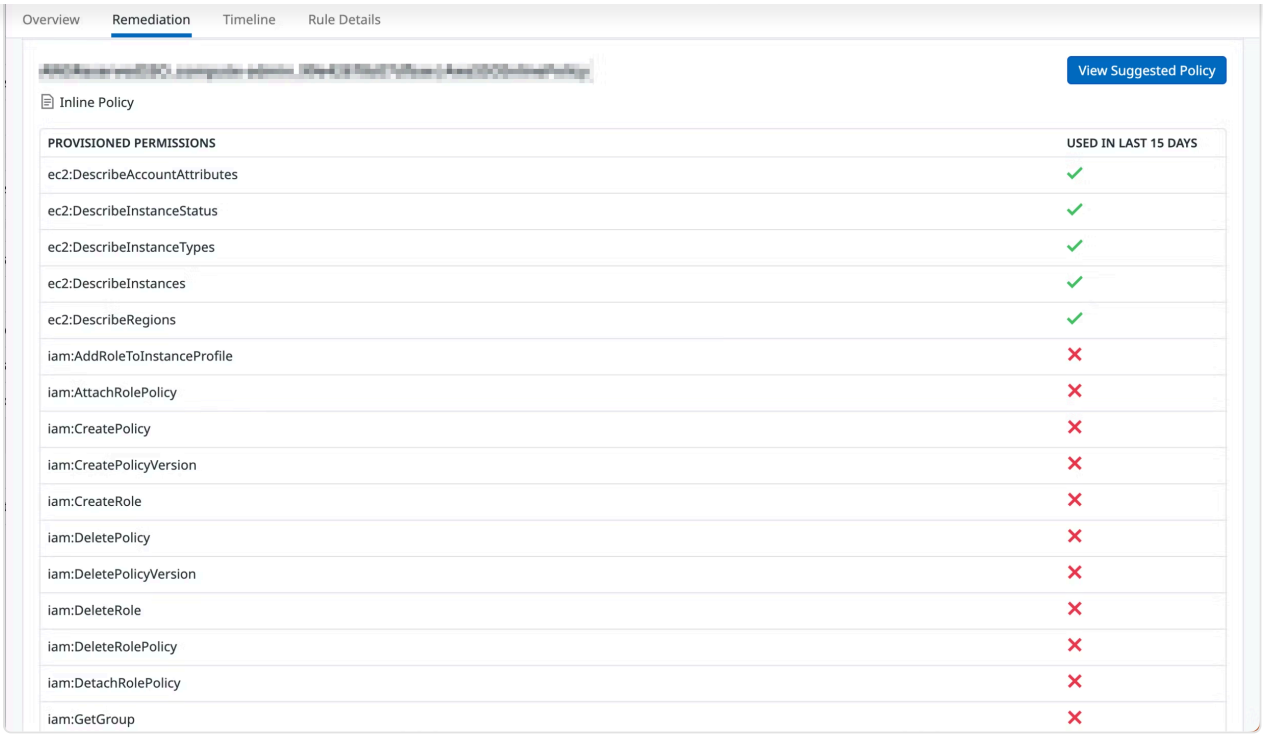

Get deeper insights to efficiently mitigate identity risks

Datadog CIEM also provides advanced insights for each identified risk, providing you with additional context for understanding its scope. For example, the following screenshot shows a list of all provisioned permissions for an IAM role that Datadog CIEM has identified as unused.

Catch up on Keynote highlights from DASH

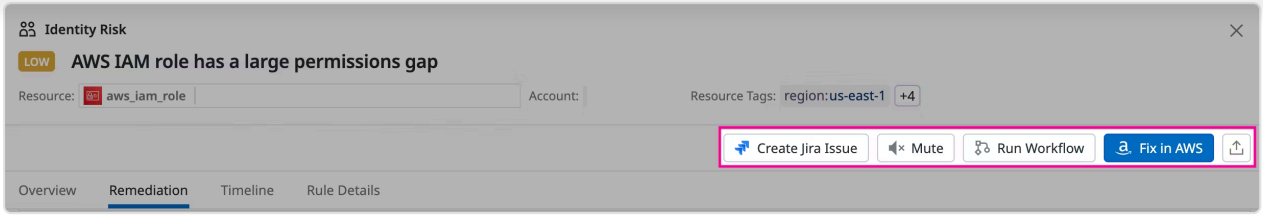

In this example, you can see that several permissions have not been used in the recent past. In these cases, you may want to remove the permissions that are no longer necessary for that role. Roles should be assigned permissions based on the principle of least privilege, which recommends granting only the set of permissions that are needed to accomplish a specific task.

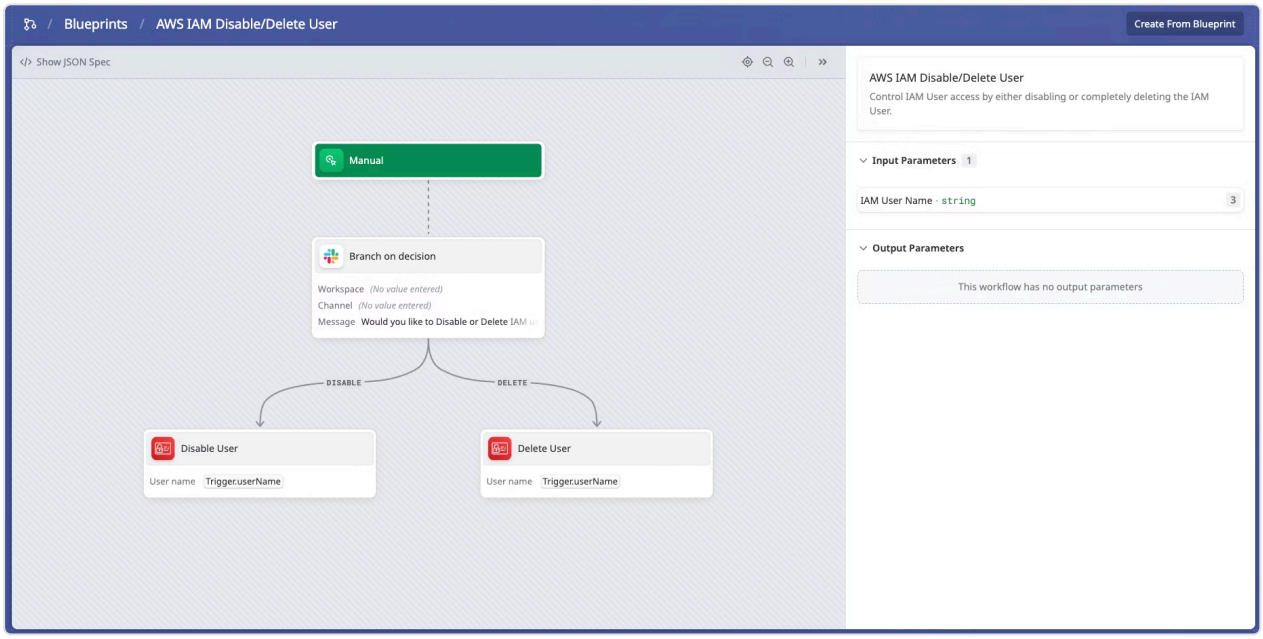

You can see AWS' suggested remediation steps by clicking the "Fix in AWS" button to navigate to the console. Alternatively, you can click “Remediate” to get a suggested downsized policy based on the actual usage.

Datadog includes several out-of-the-box Workflow Blueprints related to IAM to help you respond to identity-related risks. For example, if you discover an inactive AWS IAM user with excessive privileges, you can initiate a workflow that disables or deletes that user.

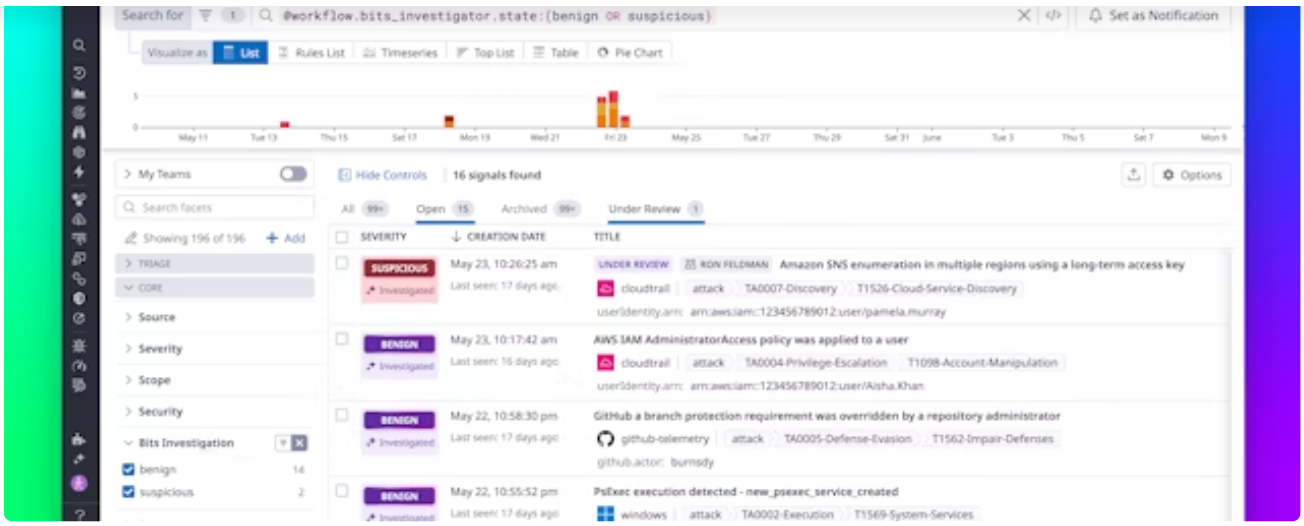

Secure your environment with Datadog Cloud Security Management

Datadog CIEM is now generally available for organizations using AWS—check out our documentation to get started, or head to the Identity Risks Explorer. You can also check out the CSM documentation for more information about getting started with Datadog Cloud Security Management. If you don't already have a Datadog account, you can sign up for a 14-day free trial today.
