In recent years, the popularity of Kubernetes deployments has surged—as has the prevalence of security risks associated with the technology. Red Hat's State of Kubernetes Security for 2023 reveals that 67 percent of organizations have encountered delays in application deployments due to Kubernetes-related security issues. Additionally, 37 percent have experienced significant revenue or customer losses stemming from Kubernetes security incidents. These trends underscore the importance of proactively monitoring your Kubernetes environment for misconfigurations and vulnerabilities to mitigate business risk.

your own custom detection policies.

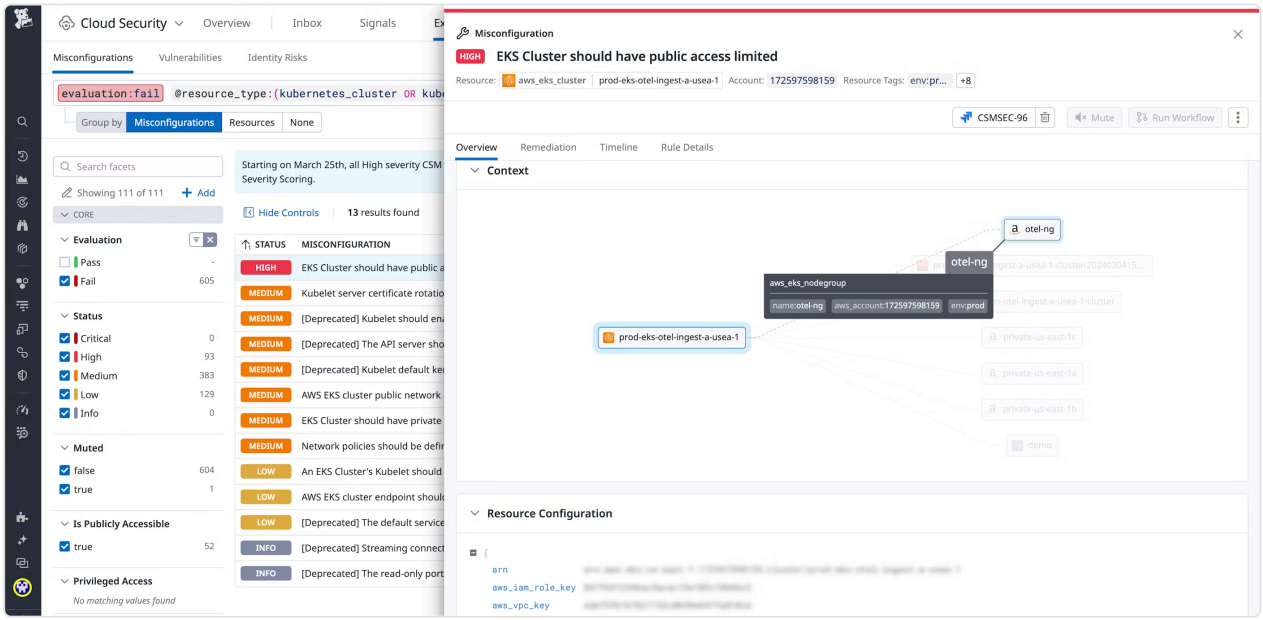

In this post, we'll show you how KSPM helps you:

- Monitor risk across Kubernetes deployments
- Assess your Kubernetes security posture against industry-standard frameworks
- Create your own Kubernetes security detections

Monitor risk across Kubernetes deployments

Datadog's security experts have curated a comprehensive list of 100+ built-in Kubernetes detection rules that are now available in CSM. These rules relieve security teams of the hard work of searching for common Kubernetes security issues and determining how best to solve them—now, Datadog will scan your environment for risks defined by these rules and offer clear descriptions of any issues detected, along with straightforward remediation guidelines.

Each finding contains all the context you need to identify the issue's impact, such as the full resource configuration, resource-level tags, and a map of the resource's relationships with other components of your infrastructure. Once you understand the problem and its impact, you can quickly start remediating the issue by creating a Jira ticket from within CSM or executing a Datadog workflow.

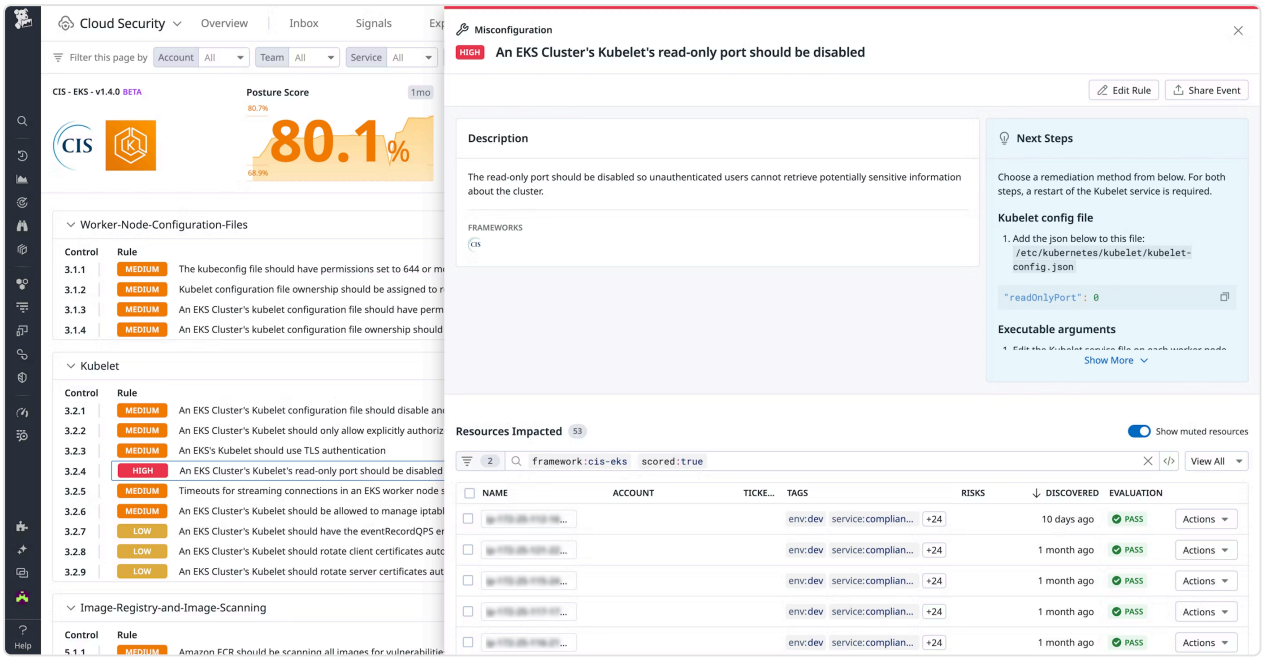

Assess your Kubernetes security posture against industry-standard frameworks

With a wide range of resources and controls for Kubernetes security available online, it can be complicated to clearly understand and evaluate what good security posture means. Datadog CSM lets you evaluate your posture against industry-standard frameworks like CIS in real time and maps out requirements and controls in an easy-to-consume report.

API to programmatically interact with the findings surfaced.

Create your own Kubernetes security detections

Each organization has unique security needs. Datadog CSM empowers you to create your own detection rules by cloning an existing control or creating one from scratch.

Rules are written in the Rego policy language, a simple but flexible Python-like language that serves as the industry standard for detection rules. As you draft your detection query, you can test it immediately against your existing Kubernetes resources to ensure the rule is accurate and works as expected.

Once your detection is ready, you can customize its severity (Critical, High, Medium, Low, or Info) and set alerts so the right people will be notified immediately of any findings for the rule.

Start monitoring Kubernetes security risks

In addition to these KSPM features, Datadog CSM also enables you to:

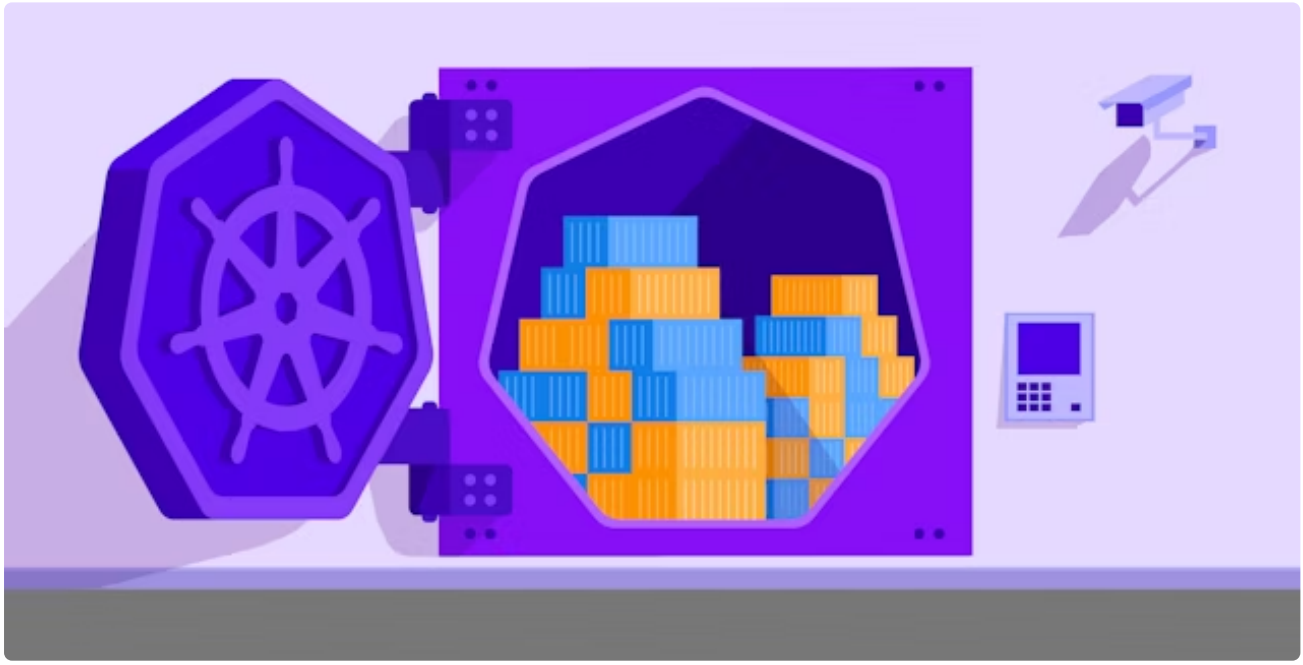

- Identify vulnerabilities in your container images and get advice on how to prioritize remediation efforts, based on whether the affected containers run in production and if attackers are likely to

processes accessing a pod's service account token, and use the existing Datadog observability context for 360-degree investigations.

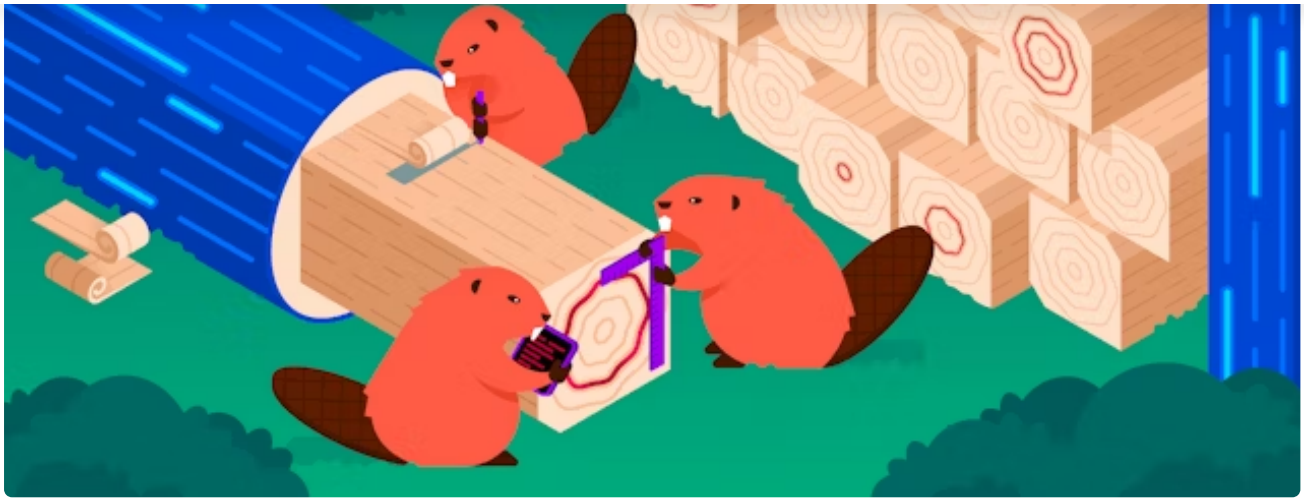

Our new KSPM frameworks are now generally available to all CSM Pro customers for AWS EKS, Azure AKS, and unmanaged Kubernetes deployments, with Google Cloud GKE support coming later this year. Check out our KSPM documentation to get started, or head to the Frameworks page in Datadog CSM. If you don't already have a Datadog account, you can sign up for a 14-day free trial today.
